2. FRONT PANEL FACILITIES

LEFT AND RIGHT OCTAVE CONTROLS

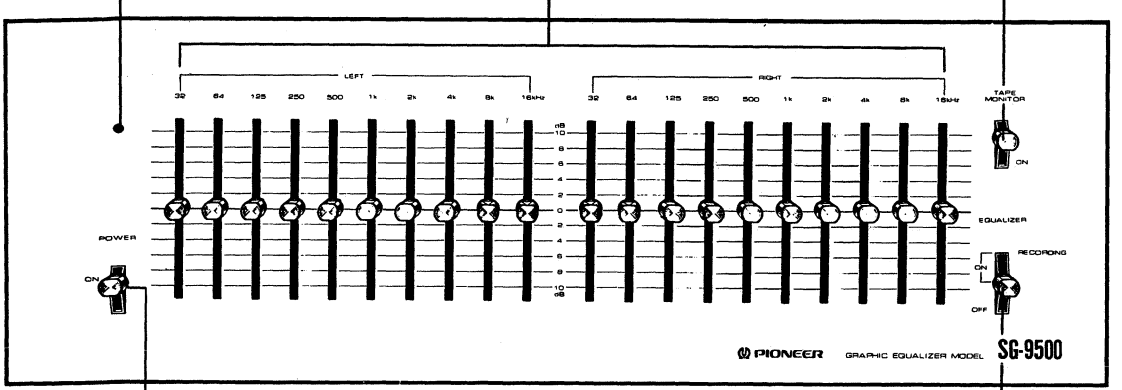
Each control provides continuous level variation of its indicated frequency from −10 dB to +10 dB. Each frequency segment becomes enhanced when its control is positioned above center (0) and attenuated when positioned below center. With all controls set to 0, the input signal is fed to the OUTPUT jacks unchanged.

PILOT LAMP

Lights when power is turned on.

TAPE MONITOR SWITCH

Set to ON to play tape or monitor recording conditions with a tape deck connected to the SG-9500. Normally set switch to OFF.



POWER SWITCH

Set to ON to energize the SG-9500. Sound will not be obtained immediately after switching on the power, due to the operation of the internal muting circuit. This does not signify a malfunction.

EQUALIZER SWITCH

OFF: Signal bypasses circuits and is not equalized.

Note

In this condition the SG-9500 is not operational, and its POWER switch may be turned OFF if required.

ON: For equalized playback of input signal.

ON/RECORDING: To record an equalized signal with a tape deck connected to SG-9500 TAPE jacks.

5. CIRCUIT DESCRIPTIONS

5.1 EQ SECTION OPERATING DESCRIPTION

The basic construction of the EQ section is shown in Fig. 1, where BPF denotes a single pole bandpass active filter incorporating an operational amplifier*. The next stage also uses an operational amplifier to form a non-inverting voltage amplifier. Its output goes to an emitter-follower transistor which provides negative feedback to the BPF input.

In this type of feedback loop, by making the loop gain sufficiently large, the gain at a frequency equal to the BPF pole becomes essentially Rnf/Rin. Thus by adjusting the variable resistor (VR) the circuit gain (or attenuation) at the BPF pole frequency can be varied.

BPF equivalent impedance is applied in the same manner to both Rin and Rnf. Hence the more the input frequency deviates from the BPF pole frequency (BPF equivalent impedance increases), the smaller the effect of Rnf and Rin on the circuit gain is provided, the circuit gain is determined by the ratio of the BPF equivalent impedance applied between Rnf and Rin.

In case illustrated in Fig. 1, since the applied impedances are the same, the circuit gain is "1" and the frequency characteristic becomes flat without regard to the BPF. However at frequencies removed from the pole frequency of the BPF, the loop gain is significantly reduced and above conditions do not apply; in these cases the frequency response falls off.

A complementary symmetrical emitter-follower buffer stage is employed in the actual circuit. This is followed by bandpass filters for each octave (total 10 elements) arranged in parallel. A variable resistor for adjusting the feedback is provided at each element to allow a peak or a dip to be produced as desired in the frequency characteristic of each octave in the audio frequency band.

**Operational Amplifier (Op-Amp)*
This type of integrated circuit is often used in analogue computers and similar systems. It features large gain over a wide frequency band, low drift and stable response to the application of feedback. By varying the input or feedback circuit, division, addition, multiplication by coefficients, plus-minus conversions, and other functions can be performed.

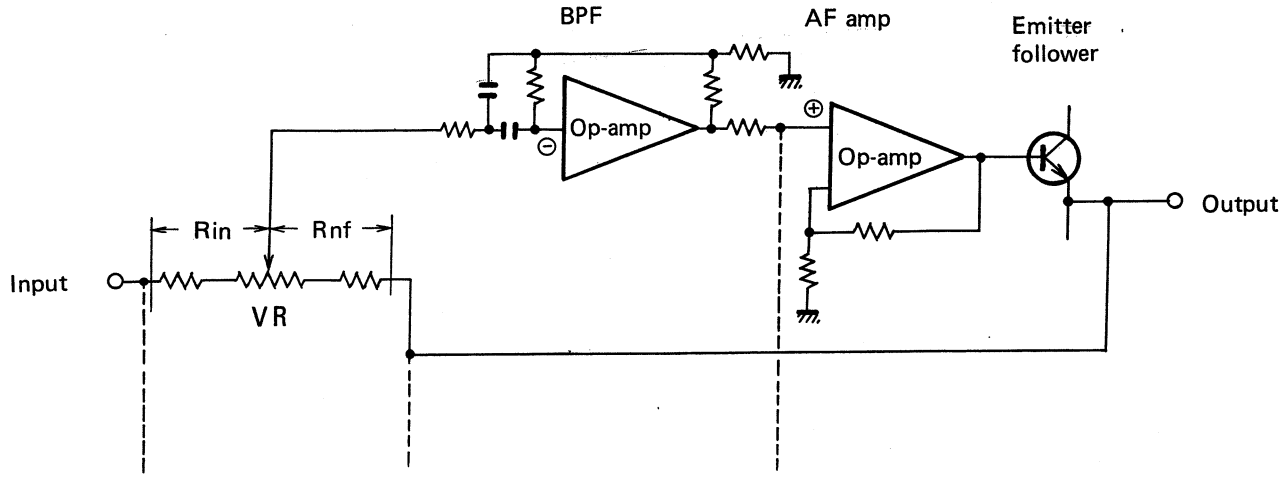

Fig. 1

5.2 MUTING CIRCUIT

A pure electronic muting circuit is provided in this unit to prevent bothersome noise when the power supply is switched ON-OFF. The muting function is performed by inserting an FET in series with the EQ section output circuit and applying a voltage to its gate. Q1 and Q2 in Fig. 2 are pnp transistors, while Q3 is a depletion type N channel junction FET which switches OFF when a negative voltage is applied to its gate.

Switching Power ON

The small charging time constant of C1 causes a positive voltage to be applied to Q1 base when the power source is switched ON, and Q1 remains in the OFF state. Since the charging time constant of C3 is also small, a negative voltage is immediately applied to Q2 collector through D3 and R3. Q2 remains OFF at this time due to the large charging time constant of C2 and insufficient bias between Q2 base and emitter. Consequently, the negative voltage at Q2 collector passes through D4 and is applied to Q3 gate. Q3 is therefore switched OFF and a muting function is obtained.

When C2 charges and sufficient bias is applied between Q2 base and emitter, Q2 switches ON. This causes Q2 collector potential to become essentially +Vcc, switching Q3 ON to release the muting.

Switching Power OFF

Since the discharge time constant of C1 is short, Q1 base potential becomes 0V almost instantaneously. During the time required for +Vcc to reach 0V, Q1 is temporarily biased between base and emitter, switching it ON. This causes C2 to discharge rapidly through Q1, switching Q2 OFF.

Since the discharge time of C3 is comparatively long, its negative charging voltage switches Q3 OFF to perform muting.

As a depletion type FET, Q3 switches ON after C3 has completely discharged. This does not present a problem since by this time Vcc has become sufficiently low and the equipment has ceased to function. Q2 collector voltage variation is shown in Fig. 3.

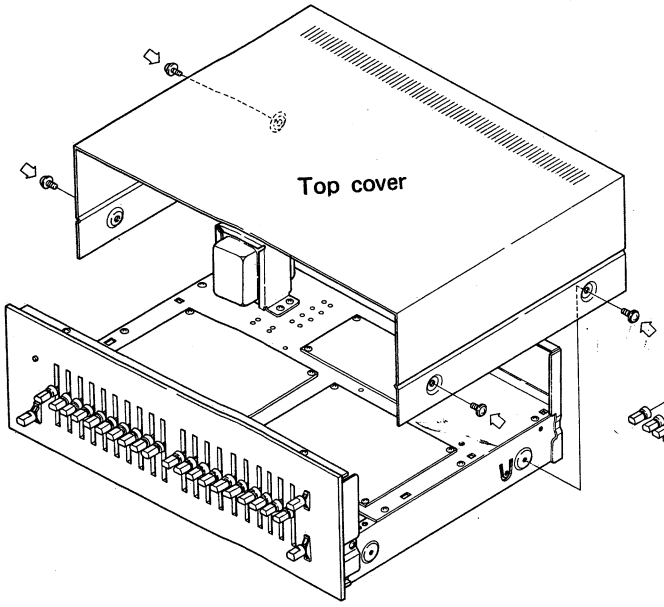
6. DISASSEMBLY

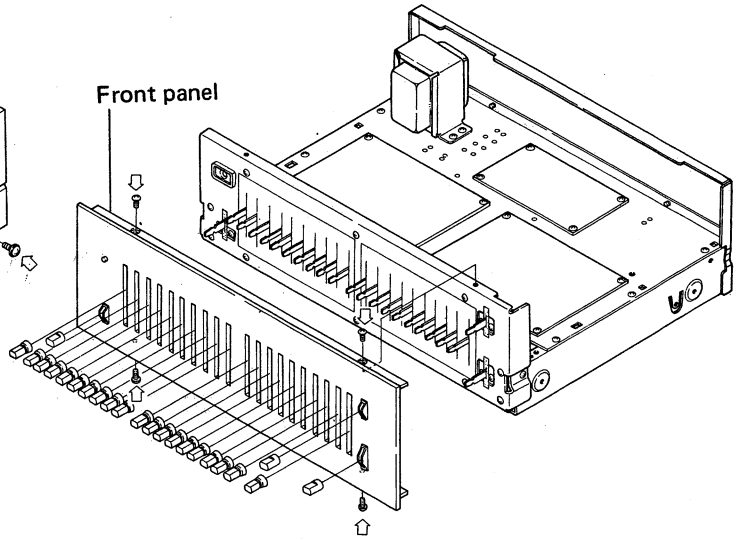
Top Cover

Remove the two screws on each side of the top cover.



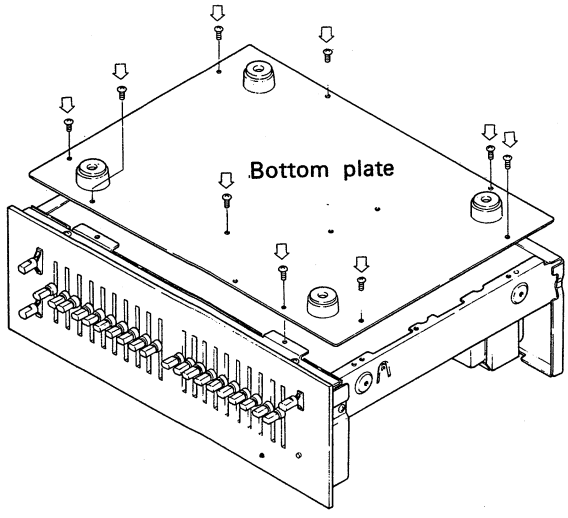
Front Panel

Remove all control knobs by pulling them out. Remove the two screws each from the top and bottom edges of the front panel.



Bottom Plate

Remove the nine screws to detach the bottom plate.



VR Assembly

Remove the top cover and front panel. Remove the six screws which mount the VR assembly on the sub-panel.
